Abstract

Nutritional problem in urban area is generally caused by food absorption disorder which can be treated by *Tui Na* massage. This article was aimed to investigate the effect of *Tui Na* massage on the growth status of children less than five years of age with KMS T status (low weight gain in Indonesia medical record). This quasi-experimental study was conducted by implementing pre-and-posttest design with control group. This study involved 26 children less than five years of age with KMS T as research samples chosen by simple random sampling technique. The results of analysis using paired t-test on the effect before and after *Tui Na* massage showed $p=0.019 < \alpha=0.05$, while independent t-test in control and treatment group obtained $p=0.065 > \alpha=0.05$. It shows that *Tui Na* massage affects the growth status of children under five years of age. Based on those results, midwives are expected to be able to perform *Tui Na* massage as an effort to develop the growth status of children under five years of age.

Introduction

All parents expect their children to grow normally. Growth is associated with the changes in quantity and size, or dimension of cells, organs, and individuals which can be measured by weight and height.¹ Positive growth will bring advantage for the children's future as the nation's next generation. On the contrary, health problem will serve as an obstacle for the continuation of the next generation.² Growth problem in Indonesia is highly associated with low nutrition and obesity. In Indonesia, millions of children under the age of five are suffered from nutritional problem.³

UNICEF noted that millions of children in Southeast Asia and South Asia are having nutritional problems. One out of three children less than five years of age are suffered growth problems (low height-for-age/stunted growth) and nearly one-fifth are

suffered from low weight below average/underweight.⁴ According to the results of the 2013 Basic Health Research Data, 18.8% of children fewer than five years of age experience low nutrition and 29% experience stunting. This prevalence rate is above the universally consented threshold published by World Health Organization (WHO), which is 20% or one-fifth of the total number of children less than five years of age in a country.

Low nutrition is a condition in which the body weight is below WHO growth curve; whereas stunting is a condition in which a child is failed to grow due to low nutrition and recurrent diseases for a long time during the fetal age until the first two years of a child's life.³ Some related factors to nutritional problems are low family income (economic factor), knowledge about food nutrition, birth spacing, prejudices against certain foods, adverse food abstinence traditions, and excessive preference for certain foods. Nutritional problems in urban areas are mostly not caused by economic factors but resulted from food absorption disorders.

Low nutrition and weight in toddlerhood will result a less optimal physical and mental health development in adulthood. Whilst, children with stunting are at risk of having an IQ of 5-10 points lower than normal children.⁵

An approach is needed to handle children growth problems by overcoming eating difficulties, safely increase the capacity to absorb nutrients and minimize the adverse effects on children. Recently, a baby massage technique, *Tui Na* massage, has been developed. This massage is performed by sliding technique (*Effleurage* or *Tui*), massaging technique (*Petrissage* or *Nie*), tapping technique (*tapotement* or *Da*), rubbing, pulling, twisting, shaking, and vibrating certain points in the body to alter the body's energy flow. *Tui Na* Massage is a specific massage technique for eating difficulties in children under five years of age by facilitating blood circulation to the spleen and digestive organs.

The results of the research by Zhen Huan Liu and Li Ting Cen in Guangzhou in 2009 showed that *Tui Na* massage has a positive effect on the development of nerves and blood circulation in infants.⁶ Similar research by Joko Widodo showed that *Tui Na* massage can facilitate the blood flow to the digestion and spleen to increase the absorption of nutrients.⁷

Wonokromo is one of the villages in Surabaya with heterogeneous communities and good health activities and health services since 2015. We chose RW (Rukun Warga or community Association) 02 in this area as

research target. In 2016, we obtained data from Posyandu (integrated health post) about the children under five years of age living in RW 02 Wonokromo. The initial research showed that most mothers with 2 or more children under five years of age in one household register do not use contraception. It resulted close birth spacing. In 2017, the researchers worked with the Nutrition Center of Puskesmas (community health center) Wonokromo concerning the nutrition problem among the children under five years of age in Wonokromo. The observation showed that there were 38 toddlers with poor nutritional status, one of them is suffered from congenital defects, two toddlers moved to other houses, and 35 toddlers lived permanently in Wonokromo village. At that time, the researchers provided assistance in the form of counseling and demonstrations related to low nutrition given during community service activities. Following the activities of Nutrition Center in the Posyandu, some toddlers did not want to eat

the supplemental food, while some others were looking out of it. We were then encouraged to study the effect of Tui Na massage on weight gain in children under five years of age. Therefore, this article provides our analysis on the effect of Tui Na massage to growth status of children less than five years of age with KMS T status.

Materials and Methods

This pre-experimental study was conducted by implementing quasi-experimental research design with pre-and-posttest design of a control group. Observations will be made after treatment to two groups: treatment group and control group. Tui Na massage intervention was given to the treatment group, whereas the control group received Effleurage massage or light stroking massage. Before the intervention of Tui Na and Effleurage massage, the children's body weight was measured as pre-test data. After the intervention of Tui Na and Effleurage massage, the body weight was measured as post-test data. This study involved 26 children under five years of age with KMS T status chosen by simple random sampling technique. The study was taken place in Wonokromo Surabaya from February to July 2018. The instrument used as the variable of the implementation of Tui Na massage is standard operating procedure (SOP). Weight scale is used to measure the dependent variable of growth status. The data were collected directly as primary data and analyzed by using paired t-test and independent t-test.

Results

The data were obtained from 26 respondents, respectively 13 respondents from the control group and 13 respondents from the treatment group. The respondents'

characteristics including age and sex were presented in Table 1 as follows, based on the pre-treatment assessment on the two groups.

Table 1 shows that almost all children were in the age of three to five years old. At this age, they have been enrolled in pre-school and doing many activities. They should have felt hungry and not hesitate to ask for food from their parents. Eating difficulties were often experienced by children in the age of one to three years.⁸ Almost half of the respondents received exclusive breastfeeding. The role of exclusive breastfeeding is very important to digestion functions and absorption of nutrients in infants up to the age of 6 months. It is in line with previous study in the IDAI ASI (a book about breastfeeding) where digestive tract maturation is stimulated by breast milk facilitated by the colostrum.⁹

According to Table 2, the average body weight of the respondents before the intervention is 9.3 kg and 10.4 kg for control and treatment group, respectively.

According to Table 3, after receiving Tui Na massage, almost all (76.9%) children had gained weight. Whilst, almost half (38.5%) in the control group gained weight.

The result of the analysis on the effect of Tui Na massage by paired t-test on the treatment group showed p value of 0.019. It showed the value of $\text{sig} < \alpha$ (0.05), which meant that there was a significant effect before and after receiving Tui Na massage to KMS T growth status among children under five years of age. Whilst, the result of analysis obtained in the control and treatment group by independent sample t-test showed the result of $p = 0.065$. This result indicated the value of $\text{sig} > \alpha$ (0.05) which means that H_0 is accepted. It shows that there was no significant effect of Tui Na massage on KMS T growth status among children under five years of age in the treatment group, and there was no effect of effleurage massage on KMS T growth status among children under five years of age in the control group (Table 4).

Discussion

The results of the analysis informed that KMS T growth status was influenced by Tui Na massage. Most mothers in the treatment group stated that following the intervention, their children sleep well, often feel hungry, and show higher appetite compared to before the intervention. It is in line with the theory on the activity of vagus nerve which affects the food absorption mechanism. The massage received by the children less than five years of age will increase a vagal tone. The research showed that children who received the massage experienced an increase in the vagal tone, so that the branches of the vagus nerve (the 10th brain nerve) will increase the level of absorbing enzymes: gastrin and insulin. Thus, food absorption activity will get better.¹⁰

Tui Na massage is also one of the non-pharmacological treatments that can increase appetite, reduce eating unwillingness, nausea, and vomit. One of its advantages compared to other types of massages is the ability to focus on specific problems and not only work on the muscles, bones and joints, but also the body's energy at a deeper level to keep it in balance. Besides, this massage has fewer side effects compared to chemical-based drugs. It is consistent with previous study that Tui Na massage is a more specific massage technique by facilitating blood circulation in spleen and digestion, through modification of needle-free acupuncture.¹¹ This technique works by placing pressure on the body's meridian points or energy flow lines so it is relatively easier to perform compared to acupuncture. Tui Na consists of 8 steps. The recommended treatment for children is once in a day for 6 consecutive days. In this study, the respondents received this massage continuously for 4 consecutive weeks.

The respondents who have received massage for 4 cycles of Tui Na massage appeared to have higher appetite, which in turn has a positive effect on increasing the

Table 1. The respondents' characteristics in the study on the effect of Tui Na massage to the growth status of children under five years of age with KMS T status.

Characteristics	Control group	Treatment group	Frequency (f)	Percentage (%)
Child's age				
6 months - 3 years	2	3	5	19.2
3 s/d 5 years	11	10	21	80.8
History of breast milk consumption				
Exclusive breastfeeding	5	6	11	42.3
No exclusive breastfeeding	8	7	15	57.6
Total	13	13	26	100

growth status, in this case is weight gain. The research on the effects of massage on weight gain showed that after the the parents give massage regularly twice in a week for 5 weeks, 11 babies experienced gained weight for more than 1000 grams.¹² In addition, the research by Dieter on the effects of massage to infants by giving the treatment to premature babies 3 times a day in 5 days with the duration of 15 minutes. It resulted in 53% greater weight gain compared to the control group. As an addition, previous study in Tawanganom Village, Magetan showed that there was an increase in the weight of the babies aged 3-5 months after receiving the massage.¹³

KMS T growth status of children under five years of age in the control group is not affected by Effleurage massage; and KMS T growth status of children under five years of age in the treatment group is also not affected by Tui Na massage. Tui Na is a series of massaging activities performed by several techniques, such as sliding (Effleurage or Tui), massaging (Petrissage or Nie), tapping (tapotement or Da), rubbing, pulling, twisting, shaking, and vibrating certain points in the body to affect the body's energy flow by holding and pressing certain body parts. Whereas Effleurage (light massage) is one of the main massage techniques that can be given to all body parts.¹¹ Effleurage aims to improve blood circulation, put pressure, and warm the abdominal muscles and improve physical and mental relaxation. Effleurage is an easy,

safe massage technique, it does not require a lot of tools and money, and it has no side effects and can be given by ourselves or with the help of others.¹⁴

The research results did not prove that Tui Na massage affects the growth status of children under five years of age in the treatment and control group. It implies some dominant factors that influence child's physical growth, namely genetic and environmental. The first three years of a child's life is a very important period because of physical growth and development (such as intelligence, motor skills, mental, social, and emotional development) is rapidly progressing in this period.¹⁵ Besides baby massage, nutritional fulfillment can affect the growth of the baby and the hormone. The baby's growth may also be affected by genetic factors, child's health, immunization, housing, environmental sanitation, chromosomal abnormalities, socio-economics condition, and medicines. Among these factors there are two uncontrollable factors, namely housing and environmental sanitation, in which both factors are likely to contribute to the growth of the baby. Good stimulation for children can be given by parents for maximum potential development. This is in line with the theory which states that the associated factors on the child's growth and development include adequate nutrition and supportive family environment as the basis for child development.¹⁶

Conclusions

Based on the results, the study concludes that Tui Na massage can affect the growth status of children under five years of age with KMS T status. In our experiment, Tui Na massage did not affect KMS T growth status of children under five years of age in the control and treatment group, Tui Na massage is effective for children under five years of age with KMS T growth status.
